

ALGORITHMS - a finite sequence of step by step instructions

- Flow Chart
- Bubble Sort - Use to put into ascending/descending order
- Work through the list by comparing pairs of adjacent items in the list
- If the items are correct, leave them
- If the items are incorrect, switch them
- Continue until you finish the first pass
- Repeat until no swaps.

- Quick Sort - Use to put into ascending/descending order
- choose the pivot using $(\frac{n+1}{2})$
- Write all the items less than the pivot (in the same order) in a sublist
- Write the pivot
- Write all the items remaining (in the same order) after the pivot
- Repeat until all items have been chosen or pivot.

- Bin Packing - Always remember to find the lower bound.
- Add all items together
- Divide by height of the bin.
- If your result is the same as the lower bound after applying the algorithm, then this is an optimal solution.

- First-Fit → Take items in the order given
- Place each item in the first available bin that can take it. Start at bin 1 every time.

- (+) Quick to apply ⊗ Not likely to be good solution

- Add all items together
- Divide by height of the bin.
- If your result is the same as the lower bound after applying the algorithm, then this is an optimal solution.

- Full-Bin → Use observation to find combinations that will fill a bin. Pack these first.
- Any remaining items to be packed using first-fit

- (+) Usually get a good solution ⊗ More difficult with more items/complex

- Binary Search - Ensure list is ordered (may have to sort)

- $\frac{n+1}{2}$, use as pivot (round up if not an integer)
- Compare midpoint with what we are trying to find
- Discard the part where it must not be
- Repeat until proven its not in the list.

GRAPHS & NETWORKS

- A graph consists of vertices/nodes which are connected by arcs/edges.

- If a graph has a number associated with each edge, this is called a weighted graph.

- The degree/valency of a vertex is the number of edges that meet at that vertex

- A trail which traverses (goes down) every arc and starts and ends at the same vertex is called an Eulerian cycle.

- A path is a walk which no vertex is visited more than once.

- A trail is a walk in which no edge is visited more than once.

- A cycle is a walk in which the end and start vertex are the same and no vertex is visited more than once.

- A Hamiltonian cycle is a cycle which includes every vertex.

- A spanning tree is a subgraph which includes all vertices and is also a tree.

- An adjacency matrix describes the number of arcs joining the corresponding vertices.

- A distance matrix has entries that represent the weight of each arc.

- Identify the shortest route

- ① Work backwards from the end node.

- ② You can only go down paths that have the same weight as the difference in the nodes

- e.g:

-

- 30 - 20 = 10 29 - 20 = 9
arc weight arc weight
is 10 ✓ is 10 X

- ③ Repeat until all vertices are connected.

- State the length once you get back to start

- Prim's Algorithm

- Use to find the minimum spanning tree.

- ① Sort arcs into ascending order of weight

- ② Consider the next arc of least weight (Remember, we do not want to form a cycle)

- ③ If there is a choice of equal weight, consider each in turn.

- ④ Repeat until all vertices are connected.

- Prim's can also be used from a table.

- Use to find the minimum spanning tree.

- ① Choose any vertex to start the tree.

- ② Select an arc of least weight that joins a vertex already in the tree to one not

- ③ Circle the lowest undeleted entry if there is a choice of equal weight, chose any

- ④ The circled entry becomes the next arc

- ⑤ Repeat 1-4 until all rows are deleted

- ⑥ List arcs in the order they were added

Dijkstra's Algorithm

- Use to find the shortest path

- Steps:

- ① Label start vertex with 0

- ② Look at all the vertices that can be reached directly from the start vertex that connect directly to temporary label with the sum of the weight.

- ③ Select the vertex with the smallest temporary label and make it permanent

- ④ Now look at all routes from the new vertex that connect directly to temporary label with the sum of the weight.

- ⑤ Choose the least weight including the original vertices to find the second node

- ⑥ Repeat until all vertices have a permanent label.

- THEN...

- Identify the shortest route

- ① Work backwards from the end node.

- ② You can only go down paths that have the same weight as the difference in the nodes

- e.g:

-

- 30 - 20 = 10 29 - 20 = 9
arc weight arc weight
is 10 ✓ is 10 X

- ③ Repeat until all vertices are connected.

- State the length once you get back to start

- Prim's Algorithm

- Use to find the minimum spanning tree.

- ① Sort arcs into ascending order of weight

- ② Consider the next arc of least weight (Remember, we do not want to form a cycle)

- ③ If there is a choice of equal weight, consider each in turn.

- ④ Repeat until all vertices are connected.

- Prim's can also be used from a table.

- Use to find the minimum spanning tree.

- ① Choose any vertex to start the tree.

- ② Select an arc of least weight that joins a vertex already in the tree to one not

- ③ Circle the lowest undeleted entry if there is a choice of equal weight, chose any

- ④ The circled entry becomes the next arc

- ⑤ Repeat 1-4 until all rows are deleted

- ⑥ List arcs in the order they were added

Route Inspection

- find the total of all the weights in the network.
- identify the odd vertices

- pair the odd vertices in all possible ways and for each pairing add the weights between each pair of nodes.

• identify the pairing for which the total weight is shortest. Add this distance to the total of the weights for the network. This is the total weight of the shortest route.

BE CAREFUL, WHEN PAIRING, THE LENGTHS MAY BE MISLEADING, AND MAY WEIGH MORE, SO EXPLORE ALL ROUTES POSSIBLE

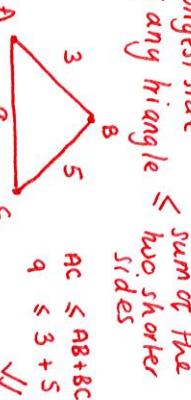

EULERIAN - if the graph has all even nodes, it is eulerian. The shortest route is the same as the total weight.

There can be a number of routes available and the question may ask for you to write your route.

*It is important that you make a note of the edges that must be repeated * (This will be the edges of the original odd vertices)

SEMI-EULERIAN - starts and finish at different nodes these nodes will both be odd. To make the network Eulerian you would need to add arcs! and these would need to be traversed twice.

represent that an activity cannot start before another time or cost, it simply happens until both 1. a path is completed. A path from source-sink = critical path

$$AC \leq AB+BC$$

$$9 \leq 3+5$$

*If you use a table of least distances then the classical and practical method are equivalent *

The Travelling Salesman

Classical Problem

: each vertex must be visited exactly once before returning to the start

triangle inequality :

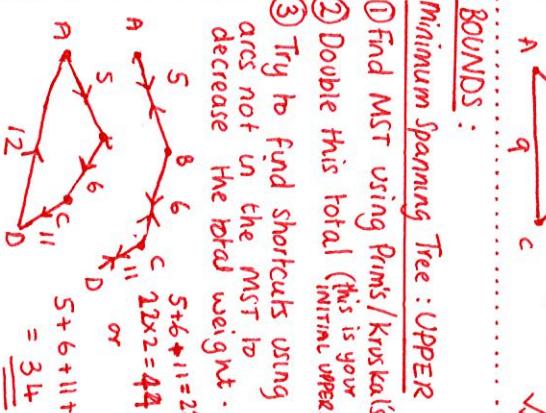

Practical Problem : each vertex must be visited at least once before returning to the start.

longest side \leq sum of the other two sides

*If you use a table of least distances then the classical and practical method are equivalent *

minimum spanning tree : upper bounds :

- ① find MST using Prim's/Kruskal's
- ② double this total (this is your initial upper bound)
- ③ try to find shortcuts using arcs not in the MST to decrease the total weight.

$$5+6+11=22$$

$$5+6+11+12 = 34$$

minimum spanning tree: lower bound :

- ① remove each vertex in turn, together with its arcs. (usually stated which)
- ② find the residual minimum spanning tree (this is just the MST after removal of one vertex)
- ③ add to the RMST 'the cost' of reconnecting with the deleted vertex using the two shortest distinct arcs and note the total.

$$\begin{array}{c} 5 \\ 4 \\ 3 \\ 6 \end{array}$$

nearest neighbour : upper bound :

- ① select each vertex in turn as a starting point (this will usually be told for which one to start)
- ② nearest neighbour - choose 1 vertex
- ③ select the arc with the least weight

- this is node 2, you can only look down this column to find the next.

- repeat until all vertices are added.

nearest neighbour : lower bound :

- ① select each vertex in turn as a starting point (this will usually be told for which one to start)
- ② nearest neighbour - choose 1 vertex
- ③ select the arc with the least weight

- this is node 2, you can only look down this column to find the next.

- repeat until all vertices are added.

critical path analysis :

- ① scheduling activities
- ② GANT charts
- ③ linear programming

critical path analysis :

- ① always make sure to find the early and late times. (happened means it is dependent)
- ② always start with node 0 is the SOURCE
- ③ float is seen

critical path analysis :

- ① always start with your critical path variables
- ② state the objective function. (maximise or minimise with objective function.)
- ③ write the constraints as inequalities.

critical path analysis :

- ① define the decision variables (x_1, y_1, z_1)
- ② state the objective function. (maximise or minimise with objective function.)
- ③ write the constraints as inequalities.

critical path analysis :

- ① graph - label feasible region
- ② for max profit, look for last point covered by objective line leaving feasible region
- ③ for min profit, look for first point covered by objective line entering feasible region
